Diffuser Tracer Test Interpretation

Group Participants: Graeme Hocking, Sarah Mitchell, Oluwaseun Francis Egbelowo, Brendan Florio Industry Representative: Maciej Starzak

January 19, 2018

Image: A math a math

Description of the problem

Cane enters at left, exits right Water/juice enters at right, exits left

・ロト ・回ト ・ ヨト

- Fibre flows through the diffuser (left to right)
- Juice flows from spray jets onto top, flowing through to be collected in trays beneath.
- Collected water is pumped upstream (in fibre) and re-sprayed
- ... but from where does the juice in each tray come?
- Experiments inputing a tracer into one of the bins were conducted ...
- MISG: Can we interpret tracer data from "dumped" salt water input?
- MISG: Produce a management-generic-interpreter in a Spreadsheet....

Underlying assumption - Model

- Treat the sugar fibres as porous medium
- Define Piezometric Head $\phi = \frac{p}{\rho g} + y$
- Apply Darcy's Law $\mathbf{q} = (u, v) = -\kappa \nabla \phi$
- Combine with conservation of volume $\nabla \cdot \mathbf{q} = \mathbf{0} \Rightarrow \nabla \cdot \kappa \nabla \phi = \mathbf{0}$
- If κ (permeability) is constant

$$\Rightarrow \nabla^2 \phi = 0$$

• Boundary conditions - on surface $y = \eta(x, t)$

$$\phi = \frac{p(x,t)}{
ho g} + \eta$$
, on $y = \eta(x,t)$

• Kinematic condition

$$\eta_t + u\eta_x - v = 0$$
 on $y = \eta(x, t)$

• Dynamic condition at bottom

$$\phi = 0$$
 on $y = 0$.

Simple linear solution

Assume the sprays are sinusoidal (just to get quick solution), so

$$\frac{p}{\rho g} = A - A\sin(\frac{\pi x}{L} - ct)$$

where c is speed of the bed, L is the distance between sprays (length of the trays) and A is the amplitude of the pressure of the sprays.

Assume
$$\phi = \int_0^\infty \sinh(ky)(a(k,t)\sin(kx) + b(k,t)\cos(kx))dk$$

and linearize about $y = D \Rightarrow \phi(x, D, t) = A - A\sin(\frac{\pi x}{L} - ct) + y$

and
$$\eta_t = -K\phi_y(x, D, t)$$

 $\phi = 0$ on y = 0 is satisfied. The solution is

$$\phi(x, y, t) = A\left[\frac{\sinh\frac{\pi y}{L}}{\sinh\frac{\pi D}{L}}\right]\sin(ct - \frac{\pi x}{L})$$

イロト イヨト イヨト イヨト

Simple linear solution (ctd)

The solution for $\eta(x, t)$ is

$$\eta(x, y, t) = D - A \frac{\pi K}{L} \left[\frac{\cosh \frac{\pi D}{L}}{\sinh \frac{\pi D}{L}} \right] \sin(ct - \frac{\pi x}{L})$$

and can work out the streamlines as

$$\psi(x, y, t) = x + A \left[\frac{\cosh \frac{\pi y}{L}}{\sinh \frac{\pi D}{L}} \right] \cos(ct - \frac{\pi x}{L})$$

Group Participants: Graeme Hocking, Sa

Streamlines t=0, t=6

Streamlines at t = 0 and t = 6.

Close together means faster flow as the pressure pulse (spray) passes overhead.

A D F A A F F

Experiment

 50 kg salt added to 200 litres of water and injected into the pipe before one of the inlet sprays

Density of $1.03 \text{kg}/\text{m}^3$ significantly higher than juice(?) so is it just a tracer?

- 240 litres of salty water then added into pipe over 5 minutes $\Rightarrow 0.05m^3/\text{min}$ added to the flow (roughly 10% increase (?)) May lead to flooding
- Conductivity measured in the bins where output is expected and 2 each side.
- Figure shows the trace from those bins.

Image: A math a math

Data were collected using conductivity probes in the bins (stages).

These data were very noisy.

Smoothing (using 6 point moving average) of the data enabled a better picture for each case.

The spread is very large along the length of the diffuser. Is this salt diffusion?

Consider a "blob" of salty water enters at the spray jet. As it travels downward it interacts with other (non-salty water) perhaps leading to salt diffusion (due to high gradient - see above)

Salt diffusion satisfies, in cylindrical polar coordinates ...

$$\frac{\partial S}{\partial t} = \frac{\alpha_S}{r} \frac{\partial^2 S}{\partial r^2}$$
 which for a point source gives $S(r, t) = \frac{1}{2\alpha_S t} e^{-r^2/4\alpha_S t}$.

where $\alpha_S = 1.5 \times 10^{-4} \ m^2/s$ (NOT molecular $\approx 10^{-9}$)

As the blob moves, $r = \sqrt{(x - ct)^2 + (y - vt)^2}$, and tracking when this arrives at the appropriate bins

<ロ> (日) (日) (日) (日) (日)

"Turbulent" Diffusion of Salt

Bins 1 to 5 left to right. Bin 3 is the target Given high salt gradient, this may be sufficent

< □ > < 🗗 > < 🖹

- The water from each spray jet enters the corresponding bin for that jet.
- The water (juice) is collected and fed into next spray upstream.
- Let $C_k(t), k = 1, 2, 3, ...$ be the concentration in each tray, and $C_0(t)$ be the upstream input concentration, then

$$\frac{C_1}{dt} = \beta \left(C_0(t - \frac{\kappa}{D}) - C_1(t) \right)$$
(1)

$$\frac{dC_2}{dt} = \beta \left(C_1(t - \frac{\kappa}{D}) - C_2(t) \right)$$
(2)

$$\frac{dC_3}{dt} = \beta \left(C_2(t - \frac{\kappa}{D}) - C_3(t) \right)$$
(3)

 $\beta = \frac{q}{V}$, $\kappa =$ permeability, q = mass flux, V = tray volume, D = fibre depth.

・ロト ・回ト ・ヨト

Ideal flow curves

・ロト ・日子・ ・ ヨト

- The water from each spray jet enters the corresponding bin for that jet, but some gets into the same bin as it started in called Recycling.
- The water (juice) is collected and fed into next spray upstream.
- The inputs to each tray are now modified as ...

$$\frac{dC_1}{dt} = \beta \left((1-\gamma)C_0(t-\frac{\kappa}{D}) + \gamma C_1(t-\frac{\kappa}{D}) - C_1(t) \right)$$
(4)

$$\frac{dC_2}{dt} = \beta \left((1-\gamma)C_1(t-\frac{\kappa}{D}) + \gamma C_2(t-\frac{\kappa}{D}) - C_2(t) \right)$$
(5)

$$\frac{dC_3}{dt} = \beta \left((1-\gamma)C_2(t-\frac{\kappa}{D}) + \gamma C_3(t-\frac{\kappa}{D}) - C_3(t) \right)$$
(6)

Image: A match the second s

・ロト ・回ト ・ヨト ・

< □ > < □ > < 三

- If the flow is perfectly matched, a succession of single bumps separated by the time of travel.
- If there is re-cycling, a second, smaller bump in Bin 1 will appear simultaneous to the primary bump in Bin 2.
- If there is by-pass, a first primary bump will appear at Bin 2 simultaneous to the primary from Bin 1.
- It would seem unlikely that both bypass and recycling will occur in the same run, except in cases very close to ideal, where there is a bit of spread ...

- Results of experiments tracing salt concentration were examined in an attempt to interpret the results.
- The spread of salt across 5 bins is too great to be caused by the flow
- Suggests the salty water is probably not acting as a tracer.
- Therefore, possible cause of the traces is either flooding (due to the extra liquid input), or...
- Salt diffusion due to turbulent interactions and the high salt content of the fluid *c.f.* surrounds (gives the best comparison).
